R QUICK REFERENCE CARD

Frequently used R commands - Version v1.1 July 2014

A first version of this qrc was created by Tom Short, EPRI PEAC, in 2004-10-21. I modified the document so it fits my other reference cards; all of its original content has been preserved or, in some cases, expanded.

Help

Most R functions have online documentation.

help(topic). documentation on topic

?topic..... id.

help.search("topic")

search the help system

apropos("topic")

the names of all objects in the search list matching the regular expression "topic"

help.start() start the HTML version of help

Fundamentals

\leftarrow assign to an object, equivalent to $=$ (?	?)
<	S-
getwd() get the working directory	
setwd() set the working directory	
<pre>system() call the operating system (shell)</pre>	
<pre>system.time()</pre>	
time an evaluation	
Sys.sleep(). pause	
str(a) display the internal [str]ucture of a R object a	n
summary(a) gives a "summary" of a, usually a statistical summary but it is <i>generic</i> meaning it has different operations for different classes of a	n-
ls() show objects in the search path; specify pat="pat" to search on a pattern	y
ls.str()str() for each variable in the search pat	th

dir() show files in the current directory

methods(a).. shows S3 methods of a methods(class=class(a))

lists all the methods to handle objects of class a

Input and output

load() load the datasets written with save

data(x)..... loads specified data set

library(x).. load add-on packages
read.table(file)

reads a file in table format and creates a data frame from it; the default separator sep="" is any whitespace;

use header=T to read the first line as a header of column names:

use as.is=T to prevent character vectors from being converted to factors;

use comment.char="" to prevent "#" from being interpreted as a comment;

use skip=n to skip n lines before reading data;

see the help for options on row naming, NA treatment, and others

read.csv("filename",header=T)

id. but with defaults set for reading comma-delimited files

read.csv2("filename",header=T,fill=T)

id. but with defaults set for reading semicolon-delimited files and dec=","; if fill is TRUE then in case the rows have unequal length, blank fields are implicitly added; if blank.lines.skip is T then blank lines in the input are ignored.

read.delim("filename",header=T)

id. but with defaults set for reading tab-delimited files

read.fwf(file,widths,header=F,sep="\t",as.is=F)
read a table of [f]ixed [w]idth [f]ormatted data into a 'data.frame'; widths is
an integer vector, giving the widths of
the fixed-width fields

save(file,...)

saves the specified objects (...) in the XDR platform-independent binary format

save.image(file)

saves all objects

cat(..., file="", sep=" ")

prints the arguments after coercing to character; sep is the character separator between arguments

format(x,...)

format an R object for pretty printing

write.table(x,file="",row.names=T,col.names=T, sep=" ")

prints x after converting to a data frame;

if quote is TRUE, character or factor

columns are surrounded by quotes (");

sep is the field separator; eol is the

end-of-line separator; na is the string

for missing values; use col.names=NA

to add a blank column header to get

the column headers aligned correctly

for spreadsheet input

sink(file) .. [output to file, until sink()] Most of the I/O functions have a file argument. This can often be a character string naming a file or a connection.

file="" means the standard input or output. Connections can include files, pipes, zipped files, and R variables.

On windows, the file connection can also be used with description = "clipboard".

 \Rightarrow To read a table copied from Excel, use:

x <- read.delim("clipboard")</pre>

 \Rightarrow To write a table to the clipboard for Excel, use:

write.table(x,"clipboard",sep="\t",col.names=NA)

For database interaction, see packages RODBC, DBI, RMySQL, RPgSQL, and ROracle. See packages XML, hdf5, netCDF for reading other file formats.

Data creation

c(...) generic function to concatenate arguments with the default forming a vector; with recursive=T descends through lists combining all elements into one vector

from:to..... generates a sequence; ":" has operator priority; 1:4 + 1 is "2,3,4,5"

seq(from,to) generates a sequence by= specifies increment; length= specifies desired length

rep(x,times) replicate x times; use each= to repeat "each" element of x each times;

 \Rightarrow rep(c(1,2,3),2): 1 2 3 1 2 3

 \Rightarrow rep(c(1,2,3),each=2): 1 1 2 2 3 3

data.frame(...)

create a data frame of the named or unnamed arguments

 \Rightarrow $\;\;$ shorter vectors are being recycled to the length of the longest:

d...ame(v=1:4,ch=c("a","B","c","d"),n=10)

list(...) ... create a list of the named or unnamed arguments

 \Rightarrow use: list(a=c(1,2),b="hi",c=3i)

array(x,dim=)

array with data x; specify dimensions like dim=c(3,4,2); elements of x recycle if x is not long enough

matrix(x,nrow=,ncol=)

matrix; elements of x recycle

factor(x,levels=)

encodes a vector \mathbf{x} as a factor

gl(n,k,length=n*k,labels=1:n)

generate levels (factors) by specifying the pattern of their levels; k is the number of levels, and n is the number of replications

expand.grid()

a data frame from all combinations of the supplied vectors or factors

rbind(...) .. combine arguments by rows for matrices, data frames, and others

cbind(...) .. id. by columns

Slicing and extracting data

Indexing vectors

x[n]	n^{th} element
x[-n]	all but the n^{th} element
x[-length(x)]	all but last element
x[1:n]	first elements
x[-(1:n)]	elements from $n+1$ to the end
x[c(1,4,2)]	specific elements
x["name"]	element named "name"
x[x > 3]	all elements greater than 3
x[x > 3 & x < 5]	all elements between 3 and 5 $$
\Rightarrow elements in	the given set:

x[x %in% c("a", "and", "the")]

Indexing lists

t with elements n
^h element of the list
ement of the list named "name"

Indexing matrices

x[i,j]	element at row $\mathtt{i},$ column \mathtt{j}
x[i,]	row i

x[,j] column j
x[,c(1,3)] columns 1 and 3
x["name",] row named "name"

Indexing data frames

matrix indexing plus the following

x[["name"]] column named "name" x\$name id.

Variable information

is.na(x), is.null(x), is.array(x), is.data.frame(x), ...

methods(is). list all available typetests

methods(as). list of all variable conversions

any(x) any TRUE elements of x?

all(x)..... all TRUE elements of x?

length(x) ... number of elements in x

rle(x)..... length of consecutive elements in x

dim(x) Retrieve or set the dimension of an object; dim(x) <- c(3,2)</pre>

dimnames(x). Retrieve or set the dimension names of an object

 $\mathtt{nrow}(\mathtt{x})$ number of rows; NROW(x) is the same but treats a vector as a one-row matrix

ncol(x)..... and

NCOL(x)..... id. for columns

unclass(x) .. remove the class attribute of x
attr(x,which)

 $\label{eq:constraints} \text{get or set the attribute which of } x$ attributes(obj)

get or set the list of attributes of obj

Data selection and manipulation

which.max(x) returns the index of the greatest element of x

which.min(x)	returns the index of the smallest element of x
rev(x)	reverses the elements of \mathbf{x}
sort(x)	sorts the elements of \mathbf{x} in increasing order
rev(sort(x))	to sort in decreasing order
<pre>cut(x,breaks)</pre>	
	divides x into intervals (factors); breaks is the number of cut intervals or a vector of cut points
x %in% y	logical vector indicating if there is a match or not for its left operand
<pre>match(x, y).</pre>	returns a vector of the same length than \mathbf{x} with the elements of \mathbf{x} which are in \mathbf{y} (NA otherwise)
which(x == a)	
	returns a vector of the indices of \mathbf{x} if the comparison operation is true (T) , in this example the values of \mathbf{i} for which $\mathbf{x}[\mathbf{i}] == \mathbf{a}$ (the argument of this function must be a variable of mode logical)
choose(n, k)	computes the combinations of k events among n repetitions = $n!/[(n-k)!k!]$
combn(n, k).	Generate All Combinations of n Elements, Taken m at a Time.
na.omit(x)	suppresses the observations with missing data (NA) (suppresses the corresponding line if ${\bf x}$ is a matrix or a data frame)
na.fail(x)	returns an error message if ${\tt x}$ contains at least one NA
unique(x)	if \mathbf{x} is a vector or a data frame, returns a similar object but with the duplicate elements suppressed
table(x)	returns a table with the numbers of the differents values of x (typically for integers or factors)
<pre>subset(x,)</pre>	
	returns a selection of x with respect to criteria (, typically comparisons: x\$V1 < 10); if x is a data frame, the option select gives the variables to be kept or dropped using a minus sign

```
ment size elements in the vector x,
               the option replace = TRUE allows to
               resample with replacement
prop.table(x,margin=)
               table entries as fraction of marginal ta-
               ble
Characters (Strings)
paste(...) .. concatenate vectors after converting to
               character; sep= is the string to sep-
               arate terms (a single space is the de-
               fault); collapse= is an optional string
               to separate "collapsed" results
substr(x,start,stop)
               substrings in a character vector
        can also assign, as:
\Rightarrow
        substr(x, start, stop) <- value</pre>
strsplit(x,split)
               split x according to the substring split
grep(pattern,x)
               searches for matches to pattern within
               x; see ?regex
gsub(pattern,replacement,x)
               replacement of matches determined by
               regular expression matching sub() is
               the same but only replaces the first oc-
               currence.
tolower(x).. convert to lowercase
toupper(x).. convert to uppercase
match(x,table)
               a vector of the positions of first matches
               for the elements of x among table
x %in% table
               id. but returns a logical vector
pmatch(x,table)
               partial matches for the elements of x
               among table
nchar(x).... number of characters
assign ...... assign a value to a name
```

resample randomly and without replace-

sample(x, size)

```
get ..... get a value from a name
eval(parse(text='1+1'))
             compute on the language!!
```

Dates and Times

%b, %B

%Υ

The class Date has dates without times. POSIXct has dates and times, including time zones. Comparisons (e.g. >), seq(), and difftime() are useful. Date also allows + and -. ?DateTimeClasses gives more information. See also package chron.

```
as.Date(s) .. and
as.POSIXct(s)
              convert to the respective class; for-
              mat(dt) converts to a string represen-
              tation. The default string format is
              "2001-02-21". These accept a second
              argument to specify a format for con-
              version. Some common formats are:
       %a. %A
                    Abbreviated and full
                    weekday name.
```

Abbreviated and full month name.

,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,	
%d	Day of the month $(01-31)$.
%Н	Hours (00–23).
%I	Hours (01–12).
%j	Day of year $(001-366)$.
%m	Month (01–12).
% M	Minute (00–59).
%p	AM/PM indicator.
%S	Second as decimal number (00–61).
%U	Week $(00-53)$; the first Sunday as day 1 of week 1.
% ₩	Weekday $(0-6, Sunday is 0)$.
%W	Week $(00-53)$; the first Monday as day 1 of week 1.
%у	Year without century (00–99).

Don't use (!)

Year with century.

%z	(output only.) Offset from Greenwich; -0800 is 8 hours west of.
%Z	(output only.) Time zone as a character string (empty if not available).
Where leading zeros are shown they will be used on output but are optional on input. See ?strftime. as.POSIXct(strptime(, format=)) format()	
Math sin,cos,tan,asin,acos,atan,atan2,log,log10,exp	
Basic Math Operations	

Basic Math Operations
%, %/% modulo/quotient, remainder
$\max(x)$ maximum of the elements of x
$\min(x)$ minimum of the elements of x
$range(x) \dots id. then c(min(x), max(x))$
$\operatorname{sum}(x)$ sum of the elements of x
$\mathtt{diff}(\mathtt{x})\dots\dots$ lagged and iterated differences of vector \mathtt{x}
$\mathtt{prod}(\mathtt{x})\dots$ product of the elements of \mathtt{x}
$\mathtt{mean}(\mathtt{x})\dots$ mean of the elements of \mathtt{x}
<pre>median(x) median of the elements of x quantile(x,probs=)</pre>
<pre>weighted.mean(x, w)</pre>
$\mathtt{rank}(\mathtt{x})$ ranks of the elements of \mathtt{x}
var(x) or $cov(x)$ variance of the elements of x (calculated on $n-1$); if x is a matrix or a data frame, the variance-covariance matrix is calculated $sd(x)$ standard deviation of x
cor(x) correlation matrix of x if it is a matrix

or a data frame (1 if x is a vector)

	• •
	y, or between the columns of x and those of y if they are matrices or data
	frames
cor(x, y)	linear correlation between x and y , or correlation matrix if they are matrices or data frames
round(x, n).	rounds the elements of ${\tt x}$ to ${\tt n}$ decimals
log(x, base)	computes the logarithm of \mathbf{x} with base base
scale(x)	if x is a matrix, centers and reduces the data; to center only use the option center=F, to reduce only scale=F (by default center=T, scale=T)
pmin(x,y,)	a vector which i th element is the minimum of $x[i]$, $y[i]$,
pmax(x,y,)	id. for the maximum
cumsum(x)	a vector which i th element is the sum from x[1] to x[i]
cumprod(x)	id. for the product
cummin(x)	id. for the minimum
$\mathtt{cummax}(\mathtt{x})\ldots$	id. for the maximum
Arithmetic & B	oolean Operator

var(x, y) ... or cov(x, y) covariance between x and

x + y	addition
х - у	subtraction
x * y	multiplication
x / y	division
x ^ y	exponentiation
x %% y	modular arithmetic
x %/% y	integer division
x == y	test for equality
x <= y	test for less-than-or-equal
x >= y	test for greater-than-or-equal
x && y	boolean and for scalars
x II y	boolean or for scalars
х & у	boolean and for vectors (vector $x,y,result$)

хІу	boolean or for vectors
	(vector x,y,result)
! x	boolean negation

 $\overline{\text{union}(x,y)}$, intersect(x,y), setdiff(x,y), setequal(x,y) is.element(el,set) "set" functions Re(x) real part of a complex number Im(x) imaginary part $Mod(x) \dots modulus; abs(x) is the same$ Arg(x) angle in radians of the complex number Conj(x)..... complex conjugate convolve(x,y) compute the several kinds of convolutions of two sequences fft(x)..... Fast Fourier Transform of an array mvfft(x)..... FFT of each column of a matrix

> applies linear filtering to a univariate time series or to each series separately of a multivariate time series

Many math functions have a logical parameter na.rm=F to specify missing data (NA) removal.

\mathbf{M}

filter(x,filter)

Matrices
%o%, outer() outer products on arrays
kronecker kronecker products on arrays
t(x) transpose
diag(x) diagonal
%*% matrix multiplication
solve(a,b) $solves a %*% x = b for x$
solve(a) matrix inverse of a
$\verb"rowsum"(x) \dots sum of rows for a matrix-like object;$
rowSums(x) is a faster version
colsum(x) sum of columns for a matrix-like ob
$\mathrm{ject};$
colSums(x) id. for columns

rowMeans(x) . fast version of row means
colMeans(x) . id. for columns

Advanced data processing and HOFs

Apply functions to elements

The base apply family of function is standardized and parallelized by the plyr package.

apply(X,INDEX,FUN=)

a vector or array or list of values obtained by applying a function FUN to margins (INDEX) of X

lapply(X,FUN)

apply FUN to each element of the list ${\tt X}$

tapply(X,INDEX,FUN=)

apply FUN to each cell of a ragged array given by X with indexes INDEX

by(data,INDEX,FUN)

apply FUN to data frame data subsetted by INDEX

The 6 common higher-order functions

Reduce(f, x, init, right = F, accumulate = F)

Filter(f, x)

Find(f, x, right = F, nomatch = NULL)

Map(f, ...)

Negate(f)

Position(f,x,right = F,nomatch = NA_integer_)

Others

 ${\tt optimise()}$.. One Dimensional Optimization

merge(a,b) .. merge two data frames by common columns or row names

xtabs(a b,data=x)

a contingency table from cross-classifying factors $\,$

aggregate(x,by,FUN)

splits the data frame x into subsets, computes summary statistics for each, and returns the result in a convenient form; by is a list of grouping elements, each as long as the variables in x

stack(x, ...) transform data available as separate columns in a data frame or list into a single column

unstack(x, ...)

inverse of stack()

reshape(x, ...)

reshapes a data frame between 'wide' format with repeated measurements in separate columns of the same record and 'long' format in separate records

 \Rightarrow use: (direction="wide") or (direction="long")

Optimization and model fitting

optim(par, fn, method = c("Nelder-Mead", "BFGS", ...): general purpose optimization; par is initial values, fn is function to optimize (normally minimize)

 ${\tt nlm(f,p)}\dots$ minimize function f using a Newton-type algorithm with starting values p

glm(formula,family=)

fit generalized linear models, specified by giving a symbolic description of the linear predictor and a description of the error distribution

⇒ see ?family: family is a description of the error distribution and link function to be used in the model

nls(formula) nonlinear least-squares estimates of the nonlinear model parameters

 $\label{eq:approx} \begin{tabular}{ll} approx(x,y=) & linearly interpolate given data points; \\ x can be an xy plotting structure \\ \end{tabular}$

 ${\tt spline(x,y=)}$ cubic spline interpolation

loess(formula)

fit a polynomial surface using local fitting

Many of the formula-based modeling functions have several common arguments: data= the data frame for the formula variables, subset= a subset of variables used in the fit, na.action= action for missing values:

"na.fail", "na.omit", or a function.

Statistics

help.search("test") gives you a range of validity tests such as t.test(), binom.test(), prop.test(), power.t.test(), pairwise.t.test(), ...

Model Analysis

The following generics often apply to model fitting functions

predict(fit,...)

predictions from fit based on input data

df.residual(fit)

returns the number of residual degrees of freedom

coef(fit) ... returns the estimated coefficients (sometimes with their standard-errors)

residuals(fit)

returns the residuals

deviance(fit)

returns the deviance

fitted(fit). returns the fitted values

logLik(fit) . computes the logarithm of the likelihood and the number of parameters

AIC(fit)..... computes the Akaike information criterion or AIC

 ${\tt aov(formula)}$ analysis of variance model

anova(fit,...)

analysis of variance (or deviance) tables for one or more fitted model objects

density(x).. kernel density estimates of x

Distributions

rnorm(n, mean=0, sd=1) Gaussian (normal) rexp(n, rate=1) exponential rgamma(n, shape, scale=1) gamma rpois(n, lambda) Poisson rweibull(n, shape, scale=1) Weibull rcauchy(n, location=0, scale=1) Cauchy rbeta(n, shape1, shape2) beta rt(n, df) ... 'Student' (t) rf(n, df1, df2) Fisher–Snedecor (F) (χ^2) rchisq(n, df) Pearson rbinom(n, size, prob) binomial rgeom(n, prob) geometric rhyper(nn, m, n, k) hypergeometric rlogis(n, location=0, scale=1) logistic rlnorm(n, meanlog=0, sdlog=1) lognormal rnbinom(n, size, prob) negative binomial runif(n, min=0, max=1) uniform rwilcox(nn. m. n) rsignrank(nn, n) Wilcoxon's statis-All these functions can be used by replacing the let-

All these functions can be used by replacing the letter \mathbf{r} with \mathbf{d} , \mathbf{p} or \mathbf{q} to get, respectively, the probability density $(\mathbf{d}func(\mathbf{x}, ...))$, the cumulative probability density $(\mathbf{p}func(\mathbf{x}, ...))$, and the value of quantile $(\mathbf{q}func(\mathbf{p}, ...))$, with $0 < \mathbf{p} < 1$.

Programming

Use curly braces {} around statements

function(arglist) expr # function definition
return(value) if(cond) expr
if(cond) cons.expr else alt.expr
for(var in seq) expr
while(cond) expr
repeat expr
break
next

do.call(funname, args)

executes a function call from the name
of the function and a list of arguments
to be passed to it

Plotting

plot(x)..... plot of the values of x (on the y-axis) ordered on the x-axis

plot(x, y).. bivariate plot of x (on the x-axis) and y (on the y-axis)

 $\mathtt{hist}(\mathtt{x}) \cdot \ldots \cdot$ histogram of the frequencies of \mathtt{x}

 $\label{eq:barplot} \begin{array}{ll} \texttt{barplot(x)} \ . \ . \ histogram \ of the \ values \ of \ x; \ use \ \texttt{horiz=F} \\ & \text{for horizontal bars} \end{array}$

dotchart(x) . if x is a data frame, plots a Cleveland dot plot (stacked plots line-by-line and column-by-column)

pie(x)..... circular pie-chart

 $\verb|boxplot(x)| \dots \verb|``box-and-whiskers"| plot$

sunflowerplot(x, y)

id. than plot() but the points with similar coordinates are drawn as flowers which petal number represents the number of points

stripplot(x) plot of the values of x on a line (an alternative to boxplot() for small sample sizes) coplot(x~| z)

bivariate plot of x and y for each value or interval of values of z

interaction.plot (f1, f2, y)

if f1 and f2 are factors, plots the means of y (on the y-axis) with respect to the values of f1 (on the x-axis) and of f2 (different curves); the option fun allows to choose the summary statistic of y (by default fun=mean)

matplot(x,y) bivariate plot of the first column of x vs. the first one of y, the second one of x vs. the second one of y, etc.

fourfoldplot(x)

visualizes, with quarters of circles, the association between two dichotomous variables for different populations (x must be an array with $\dim (2, 2, k)$, or a matrix with $\dim (2, 2)$ if k = 1)

assocplot(x) Cohen-Friendly graph showing the deviations from independence of rows and columns in a two dimensional contingency table

mosaicplot(x)

'mosaic' graph of the residuals from a log-linear regression of a contingency table

 $\label{eq:plot.ts} \begin{tabular}{ll} \tt plot.ts(x) ... if x is an object of class "ts", plot of x with respect to time, x may be multivariate but the series must have the same frequency and dates x and x dates x is an object of class "ts", plot of x with respect to time, x may be multivariate but the series must have the same frequency and dates x for x dates. x is an object of class "ts", plot of x with respect to time, x may be multivariate but the series must have the same frequency and dates. x for x dates x dat$

 $\begin{tabular}{ll} ts.plot(x) ... id. but if x is multivariate the series \\ may have different dates and must have \\ the same frequency \\ \end{tabular}$

 $\begin{array}{c} \mathtt{qqnorm(x)} \ \dots \ \mathrm{quantiles} \ \mathrm{of} \ x \ \mathrm{with} \ \mathrm{respect} \ \mathrm{to} \ \mathrm{the} \ \mathrm{values} \\ \mathrm{expected} \ \mathrm{under} \ \mathrm{a} \ \mathrm{normal} \ \mathrm{law} \end{array}$

qqplot(x, y) quantiles of y with respect to the quantiles of x

contour(x, y, z)

contour plot (data are interpolated to draw the curves), x and y must be vectors and z must be a matrix so that dim(z)=c(length(x), length(y)) (x and y may be omitted)

filled.contour(x, y, z)

id. but the areas between the contours are coloured, and a legend of the colours is drawn as well

image(x, y, z)

id. but with colours (actual data are plotted)

persp(x, y, z)

id. but in perspective (actual data are plotted)

symbols(x, y, ...)

draws, at the coordinates given by x and y, symbols (circles, squares, rectangles, stars, thermometres or "boxplots") which sizes, colours ... are specified by supplementary arguments

termplot(mod.obj)

plot of the (partial) effects of a regression model (mod.obj)

Plot Modifiers

The following parameters are common to many plotting functions

add=F if TRUE superposes the plot on the previous one (if it exists)

axes=T if FALSE does not draw the axes and the box

type="p" specifies the type of plot, "p":

points, "1": lines, "b": points connected by lines, "o": id. but the lines are over the points, "h": vertical lines, "s": steps, the data are represented by the top of the vertical lines, "S": id. but the

data are represented by the bottom of the vertical lines

xlim=, ylim= specifies the lower and upper limits of the axes, for example with

xlim=c(1, 10) or xlim=range(x)

xlab=, ylab= annotates the axes, must be vari-

ables of mode character

main = main title, must be a variable of

mode character

sub= sub-title (written in a smaller font)

Low-level plotting commands

dev.new() ... open a new graphics device (typically a window). see similar in help.

points(x, y) adds points (the option type= can be used)

lines(x, y). id. but with lines

text(x, y, labels...)

adds text given by labels at coordinates (x,y); a typical use is: plot(x, y, type="n"); text(x, y, names)

mtext(text, side=3, line=0, ...)

adds text given by text in the margin specified by side (see axis() below); line specifies the line from the plotting area

segments(x0, y0, x1, y1)

draws lines from points (x0,y0) to points (x1,y1)

arrows(x0, y0, x1, y1, angle= 30, code=2)

id. with arrows at points (x0,y0) if code=2, at points (x1,y1) if code=1, or both if code=3; angle controls the angle from the shaft of the arrow to the edge of the arrow head

abline(a,b). draws a line of slope b and intercept a

abline(h=y). draws a horizontal line at ordinate y

abline(v=x) . draws a vertical line at abcissa x
abline(lm.obj)

draws regression line given by lm.obj

rect(x1, y1, x2, y2)

draws a rectangle which left, right, bottom, and top limits are x1, x2, y1, and y2, respectively

polygon(x, y)

draws a polygon linking the points with coordinates given by x and y

legend(x, y, legend)

adds the legend at the point (x,y) with the symbols given by legend. You may as well add "bottom", "topleft" etc. in place of coordinates x,y manually

title()..... adds a title and optionally a sub-title axis(side, vect)

adds an axis at the bottom (side=1), on the left (2), at the top (3), or on the right (4); vect (optional) gives the abcissa (or ordinates) where tick-marks are drawn

rug(x) draws the data x on the x-axis as small vertical lines

locator(n, type="n", ...)

returns the coordinates (x,y) after the user has clicked n times on the plot with the mouse; also draws symbols (type="p") or lines (type="l") with respect to optional graphic parameters (...)

 \Rightarrow $\,\,$ by default nothing is drawn: type="n"

Graphical parameters

These can be set globally with par(...); many can be passed as parameters to plotting commands.

bg specifies the colour of the background (ex.: bg="red", bg="blue", the list of the 657 available colours is displayed with colors())
bty controls the type of box drawn around the plot, allowed values are: "o", "l", "7", "c", "u" or "]" (the box looks like the corresponding character) ⇒ if bty="n": the box is not drawn
cex a value controlling the size of texts and symbols with respect to the default;
the following parameters have the same control for numbers on the axes, cex.axis, the axis labels, cex.lab, the title, cex.main, and the sub-title, cex.sub
col controls the color of symbols and lines; use color names e.g. "red", "blue" or as "#RRGGBB"
<pre>⇒ see: colors(), rgb(), hsv(), gray() and rainbow()</pre>
\Rightarrow as for cex there are: col.axis, col.lab, col.main, col.sub
font an integer which controls the style of text (1: normal, 2: italics, 3: bold, 4: bold italics)
<pre>⇒ as for cex there are: font.axis, font.lab, font.main, font.sub</pre>
las an integer which controls the orientation of the axis labels (0: parallel to the axes, 1: horizontal, 2: perpendicular to the axes, 3: vertical)
<pre>lty</pre>
lwd a numeric which controls the width of lines, default 1

t t c	a vector of 4 numeric values which con- crol the space between the axes and the border of the graph of the form c(bottom, left, top, right), the de- cault values are c(5.1, 4.1, 4.1, 2.1)
I t	a vector of the form c(nr,nc) which partitions the graphic window as a ma- crix of nr lines and nc columns, the plots are then drawn in columns
${\tt mfrow} \dots \dots i$	d. but the plots are drawn by row
i	controls the type of symbol, either an integer between 1 and 25, or any single character within ""
•	an integer which controls the size in points of texts and symbols
t	a character which specifies the type of the plotting region, "s": square, "m": maximal
t t	a value which specifies the length of cick-marks on the axes as a fraction of the smallest of the width or height of the plot; if tck=1 a grid is drawn
t t	a value which specifies the length of cick-marks on the axes as a fraction of the height of a line of text (by default tccl=-0.5)
	f xaxt="n" the x-axis is set but not drawn (useful in conjonction with axis(side=1,))
	f yaxt="n" the y-axis is set but not drawn (useful in conjonction with axis(side=2,))

Lattice (Trellis) graphics

Use panel= to define a custom panel function (see apropos("panel") and ?llines). Lattice functions return an object of class trellis and have to be printed to produce the graph. Use print(xyplot(...)) inside functions where automatic printing doesn't work. Use lattice.theme and lset to change Lattice defaults.

 ${\tt xyplot(y^x)}$. bivariate plots (with many functionalities)

barchart(y~x)

histogram of the values of y with respect to those of x

dotplot(y~x) Cleveland dot plot (stacked plots lineby-line and column-by-column)

densityplot(~x)

density functions plot

histogram(~x)

histogram of the frequencies of x

bwplot(y~x). "box-and-whiskers" plot

 $\mbox{\tt qqmath(~x)}$.. quantiles of x with respect to the values expected under a theoretical distribution

stripplot(y~x)

single dimension plot, x must be numeric, y may be a factor

splom(~x) ... matrix of bivariate plots

parallel(~x) parallel coordinates plot

levelplot(z~x*y|g1*g2)

coloured plot of the values of **z** at the coordinates given by **x** and **y** (**x**, **y** and **z** are all of the same length)

wireframe(z~x*y|g1*g2)

3d surface plot

 $cloud(z^*x*y|g1*g2)$

3d scatter plot

In the normal Lattice formula, y x|g1*g2 has combinations of optional conditioning variables g1 and g2 plotted on separate panels. Lattice functions take many of the same arguments as base graphics plus also data=the data frame for the formula variables and subset=for subsetting.
