## R QUICK REFERENCE CARD

Frequently used R commands – Version v1.4 September 2016

A first version of this qrc was created by Tom Short, EPRI PEAC, in 2004-10-21. I modified the document so that it fits my other reference cards; all of its original content has been preserved and, in some cases only, expanded.

## Help

Most R functions have online documentation.

help(topic)..documentation on topic

?topic ..... id.

help.search("topic")

search the help system

apropos("topic") the names of all objects in the search list matching the regular expression "topic"

help.start() start the HTML version of help

# Input and output

Most of the I/O functions have a file argument. This can often be a character string naming a file or a connection. file="" means the standard input or output. Connections can include files, pipes, zipped files, and R variables.

# Basic Operations

 $<\!\!\!-\dots$  assign to an object, equivalent to =(?)

<--....lexical assignment (\*NOT\* global assignment)

 $\mathtt{getwd}()$  ..... get the working directory

setwd() ..... set the working directory

 ${\tt system()}$  ..... call the operating system (shell)

Sys.Date()...Retreive current date, without time

system.time() time an evaluation

Sys.sleep()..pause

str(a) ...... display the internal [str]ucture of an R object a

summary(a)... gives a "summary" of a, usually a statistical summary but it is *generic* meaning it has different operations for different classes of a

ls() ...... show objects in the search path; specify pat="pat" to search on a pattern

 ${\tt ls.str()} \ldots str()$  for each variable in the search path

dir().....show files in the current directory

methods(a)...shows S3 methods of a methods(class=class(a))

lists all the methods to handle objects of class a

## Fundamentals

load() ..... load the datasets written with save

data(x) ..... loads specified data set

library(x)...load add-on packages

save.image(file) saves all objects

cat(..., file="", sep=" ")

prints the arguments after coercing to character; sep is the character separator between arguments

format(x,...) format an R object for pretty printing

sink(file)...output to file, until sink()

## Read from File

read.table(file) reads a file in table format and creates a data frame from it; the default separator sep="" is any whitespace

read.csv("filename",header=T)

id. but with defaults set for reading comma-delimited files

read.csv2("filename",header=T)

id. but with defaults set for reading semicolon-delimited files and dec=","

read.delim("filename",header=T)

id. but with defaults set for reading tab-delimited files

read.fwf(file,widths,header=F,sep="\t",as.is=F)
read a table of [f]ixed [w]idth [f]ormatted data into a 'data.frame'; widths is
an integer vector, giving the widths of
the fixed-width fields

## Read Options

- as.is=TRUE

to prevent character vectors from being converted to factors

- blank.lines.skip=TRUE
blank lines in the input are ignored.

- fill=TRUE

in case the rows have unequal length, blank fields are implicitly added

- header=TRUE

to read the first line as a header of column names

- comment.char=""

to prevent "#" from being interpreted as a comment

- skip=n to skip n lines before reading data

## Write to file

write.table(x,file="",row.names=T,col.names=T, sep=" ")
 prints x after converting to a data frame;
 if quote is TRUE, character or factor
 columns are surrounded by quotes (");
 sep is the field separator; eol is the
 end-of-line separator; na is the string
 for missing values; use col.names=NA
 to add a blank column header to get
 the column headers aligned correctly
 for spreadsheet input

# ${\bf Clipboard}$

On windows, the file connection can also be used with description = "clipboard".

- ⇒ To read a table copied from Excel, use: x <- read.delim("clipboard")</pre>
- $\Rightarrow$  To write a table to the clipboard for Excel, use:

write.table(x,"clipboard",sep=" $\t^{"}$ ,col.names=NA)

Unix users wishing to write to the primary selection may be able to do so via 'xclip', for example by

⇒ writes data 'x' to clipboard: pipe('xclip -i', x)

For database interaction, see packages RODBC, DBI, RMySQL, RPgSQL, and ROracle. See packages XML, hdf5, netCDF for reading other file formats.

rbind(...)...combine arguments by rows for matrices, data frames, and others

cbind(...)...id. by columns

⇒ append column named ''colName'' to matrix x: cbind(x, colName=c(1,2,3))

## Dates and Times

The class Date has dates without times. POSIXct has dates and times, including time zones. Comparisons (e.g. >), seq(), and difftime() are useful. Date also allows + and -. ?DateTimeClasses gives more information. See also package chron.

```
as.Date(s)...and
```

%m

- as.POSIXct(s) convert to the respective class; format(dt) converts to a string representation. The default string format is "2001-02-21". These accept a second argument to specify a format for conversion. Some common formats are:
  - %a, %A Abbreviated and full weekday name.
    %b, %B Abbreviated and full month name.
    %d Day of the month (01-31).
    %H Hours (00-23).
    %I Hours (01-12).
    - %j Day of year (001–366).

Month (01–12).

%M Minute (00–59).

```
AM/PM indicator.
q%
%S
            Second as decimal number (00-
            61).
%U
            Week (00-53): the first Sunday
            as day 1 of week 1.
%₩
            Weekday (0-6, \text{Sunday is } 0).
            Week (00–53); the first Monday
%W
            as day 1 of week 1.
            Same as "%Y-%m-%d"
%X
%v
            Year without century (00–99).
            (Don't use due to ambiguousness!)
            Year with century.
%Y
%z
            (output only.) Offset from Green-
            wich: -0800 is 8 hours west of.
%Z
            (output only.) Time zone as a
            character string (empty if not avail-
            able).
```

Where leading zeros are shown they will be used on output but are optional on input. See ?strftime. as.POSIXct( strptime( , format= ) ) format()

Setting the C locale will overcome NA issues which emerge on some systems due to format incongruencies:

```
lct <- Sys.getlocale('LC_TIME')
Sys.setlocale('LC_TIME', 'C')
x <- "1919-01-31"
as.Date(x,...)
...
Sys.setlocale('LC_TIME', lct)</pre>
```

## Indexing Data

### vectors

```
x[n] n^{th} element

x[-n] all but the n^{th} element

x[-length(x)] all but last element

x[1:n] first elements

x[-(1:n)] elements from n+1 to the end

x[c(1,4,2)] specific elements
```

```
x["name"] element named "name"
x[x > 3] all elements greater than 3
x[x > 3 & x < 5] all elements between 3 and 5

⇒ elements in the given set:
x[x %in% c("a","and","the")]

lists

x[n] list with elements n
x[[n]] n<sup>th</sup> element of the list
```

id.

element of the list named "name"

### matrices and data frames

x[["name"]]

x\$name

```
x[i,j] element at row i, column j
x[i,] row i
x[,j] column j
x[,c(1,3)] columns 1 and 3
x["name",] row named "name"
x[,"name"] column named "name"

> x$name or x[["name"]]: id.
```

## Generating and Extracting Data

### Data creation

- c(...) ...... generic function to concatenate arguments with the default forming a vector; with recursive=T descends through lists combining all elements into one vector
- from:to..... generates a sequence; ":" has operator priority; 1:4 + 1 is "2,3,4,5"
- seq(from,to) generates a sequence by= specifies increment; length= specifies desired length
- rep(x,times) replicate x times; use each= to repeat
   "each" element of x each times;
- $\Rightarrow$  rep(c(1,2,3),2): 1 2 3 1 2 3
- $\Rightarrow$  rep(c(1,2,3),each=2): 1 1 2 2 3 3
- data.frame(...) create a data frame of the named or unnamed arguments
- $\Rightarrow$   $\;$  shorter vectors are being recycled to the length of the longest:
  - d...ame(v=1:4,ch=c("a","B","c","d"),n=10)
- list(...) .... create a list of the named or unnamed arguments
- $\Rightarrow$  use: list(a=c(1,2),b="hi",c=3i)
- array(x,dim=) array with data x; specify dimensions like dim=c(3,4,2); elements of x recycle if x is not long enough
- matrix(x,nrow=,ncol=)

matrix; elements of  $\mathbf{x}$  recycle

factor(x,levels=)

encodes a vector  ${\tt x}$  as a factor

gl(n,k,length=n\*k,labels=1:n)

generate levels (factors) by specifying the pattern of their levels;  ${\tt k}$  is the number of levels, and  ${\tt n}$  is the number of replications

expand.grid() a data frame from all combinations of the supplied vectors or factors

### Variable information

is.na(x), is.null(x), is.array(x), is.data.frame(x), ...

methods(is)..list all available typetests

methods(as)..list of all variable conversions

any(x) ..... any TRUE elements of x?

all(x) ...... all TRUE elements of x?

length(x)....number of elements in x

rle(x) ..... length of consecutive elements in x

dim(x) ...... Retrieve or set the dimension of an object;  $dim(x) \leftarrow c(3,2)$ 

dimnames (x).. Retrieve or set the dimension names of an object

ncol(x) ..... and

NCOL(x) ..... id. for columns

 $\mathtt{unclass}(\mathtt{x})\dots\mathtt{remove}$  the class attribute of  $\mathtt{x}$ 

 $\mathtt{attr}(\mathtt{x}\mathtt{,which}) \qquad \mathrm{get} \ \mathrm{or} \ \mathrm{set} \ \mathrm{the} \ \mathrm{attribute} \ \mathtt{which} \ \mathrm{of} \ \mathtt{x}$ 

attributes(x) get or set the list of attributes of x

# Characters (Strings)

substr(x,start,stop)

substrings in a character vector  $\mathbf{v}$ 

⇒ can also assign, as: substr(x, start, stop) <- value</pre>

strsplit(x,split)

split x according to the substring split

grep(pttrn,x) searches for matches to pattern
 within x; see ?regex

gsub(pttrn,replmt,x)

replacement of matches determined by regular expression matching sub() is the same but only replaces the first occurrence.

tolower(x)...convert to lowercase

toupper(x)...convert to uppercase

nchar(x).... number of characters

assign ...... assign a value to a name

get ......get a value from a name
eval(parse(text='1+1'))

compute on the language!!

- na.strings

what to do with missing data ("NA")

- as.is if TRUE: strings, else: factors
- dec decimal specifier: '.' or ','
- numerals

"allow.loss", "warn.loss", "no.loss"

⇒ convert from character to numerical vector: type.convert(dax, na.strings = "NA", as.is = TRUE, dec = ",")

### Most common commands

which.max(x) returns the index of the greatest element of x

which.min(x) returns the index of the smallest element of x

rev(x) ...... reverses the elements of x
order(x), sort(x)

shows numerical order, sorts the elements of  $\mathbf{x}$  in increasing order

 $\Rightarrow$  to sort in decreasing order: rev(sort(x))

cut(x,breaks) divides x into intervals (factors);
 breaks is the number of cut intervals
 or a vector of cut points

- $x \%in\% y \dots$  logical vector indicating if there is a match or not for its left operand
- which(x == a) returns a vector of the indices of
   x if the comparison operation is true
   (T), in this example the values of i for
   which x[i] == a (the argument of this
   function must be a variable of mode
   logical)
- choose(n, k) computes the combinations of k events among n repetitions = n!/[(n-k)!k!]
- combn(n, k)..generate all combinations of n elements, taken m at a time.
- $\mathtt{na.omit(x)} \ldots \mathtt{suppresses}$  the observations with missing data (NA) (suppresses the corresponding line if x is a matrix or a data frame)
- complete.cases(x[n],x[n])
  allows removement of 'na's by using part of the dataframe
- ⇒ skip all rows in data frame x, where 'na'
  appears in column 5 or 6:
  x[complete.cases(x[,5:6]),]
- na.fail(x)...returns an error message if x contains
   at least one NA
- $\mathtt{unique}(\mathtt{x})\ldots$  if  $\mathtt{x}$  is a vector or a data frame, returns a similar object but with the duplicate elements suppressed
- duplicated(x) returns a logical vector indicating which elements (rows) of a vector or data frame are duplicates
- table(x) ..... returns a table with the numbers of the differents values of x (typically for integers or factors)
- ⇒ subset(x, Temp > 80 & Temp < 120, ...): combine more than one subset argument with logical operators.

- ⇒ select: if x is a data frame, the option select gives the variables to be kept (or dropped, using a minus sign).
- sample(x, size) resample randomly and without replacement size elements in the vector
  x, the option replace = TRUE allows
  to resample with replacement

# prop.table(x,margin=)

table entries as fraction of marginal table

### Math

sin,cos,tan,asin,acos,atan,atan2,log,log10,exp

## Basic Math Operations

- %%, %/%..... modulo/quotient, remainder
- max(x) ..... maximum of the elements of x
- min(x) ..... minimum of the elements of x
- range(x)....id. then c(min(x), max(x))
- sum(x) ..... sum of the elements of x
- Mod(x) or abs(x)

absolute value of x

- diff(x)..... lagged and iterated differences of vector x
- prod(x) ..... product of the elements of x
- mean(x) ..... mean of the elements of x
- median(x)....median of the elements of x
  quantile(x,probs=)

sample quantiles corresponding to given probabilities (default: 0,.25,.5,.75,1)

## weighted.mean(x, w)

mean of x with weights w

- rank(x) ..... ranks of the elements of x
- var(x) or cov(x) variance of the elements of x (calculated on n-1); if x is a matrix or a data frame, the variance-covariance matrix is calculated
- sd(x).....standard deviation of x
- cor(x) ...... correlation matrix of x if it is a matrix or a data frame (1 if x is a vector)
- $\mathtt{acf}(\mathtt{x})$  ...... Computes (and by default plots) estimates of the autocovariance or autocorrelation function

- round(x, n)..rounds the elements of x to n decimals

•	computes the logarithm of $\mathbf{x}$ with
	pase base
	if $x$ is a matrix, centers and reduces
•	the data; to center only use the option
	center=F, to reduce only scale=F (by
	default center=T, scale=T)
-	a vector which ith element is the min-
	imum of x[i], y[i],
pmax(x,y,).	id. for the maximum
cumsum(x)	a vector which $i$ th element is the sum
:	from $x[1]$ to $x[i]$
cumprod(x)	id. for the product
cummin(x)	id. for the minimum
cummax(x)	id. for the maximum
A 1.1	

### Arithmetic & Boolean Operators

noure & Boorean	o peracers
x + y	addition
х - у	subtraction
x * y	multiplication
х / у	division
x ^ y	exponentiation
x %% y	modular arithmetic
x %/% y	integer division
X %*% Y	matrix multiplication
x == y	test for equality
x != y	test for inequality
x <= y	test for less-than-or-equal
x >= y	test for greater-than-or-equal
x && y	boolean and for scalars
x II y	boolean or for scalars
х & у	boolean and for vectors (vector $x,y,result$ )
хІу	boolean or for vectors (vector x,y,result)
! x	boolean negation

# Complex Numbers

 $\overline{\text{union}(x,y)}$ , intersect(x,y), setdiff(x,y), setequal(x,y)

```
is.element(el,set)
               "set" functions
 Re(x)....real part of a complex number
 Im(x)....imaginary part
 Arg(x) ..... angle in radians of the complex number
 Conj(x) ..... complex conjugate
                  compute the several kinds of con-
 convolve(x,y)
               volutions of two sequences
fft(x) ...... Fast Fourier Transform of an array
 mvfft(x).....FFT of each column of a matrix
Many math functions have a logical parameter na.rm=F
to specify missing data (NA) removal.
```

Matrices
%o%, outer() outer products on arrays
A %*% B multiplication of A and B
kronecker()kronecker products on arrays
⇒ Kronecker product of A with her own inverted matrix: kronecker(A, solve(A))
t(x)transpose
diag(x) diagonal
det(a) matrix determinant of a
solve(a,b)solves a %*% x = b for x
solve(a) matrix inverse of a
rowsum(x) sum of rows for a matrix-like object:

rowSums(x)...is a faster version colsum(x)....sum of columns for a matrix-like object;

colSums(x)...id. for columns

rowMeans(x)...fast version of row means

colMeans(x)..id. for columns

# Advanced data processing and HOFs

# Apply functions to elements

The following section covers the most common commands: lapply as well as apply itself. Regarding the missing functions [m,r,s,t,v] apply consult the R-help pages. The base apply family of function is standardized and parallelized by the plyr package.

by(data,INDEX,FUN)

apply FUN to data frame data subsetted by INDEX

apply FUN to each element of the lapply(X,FUN) list X

apply(X,INDEX,FUN=)

a vector, array or list of values obtained by applying a function FUN to margins (INDEX) of X

# Options for INDEX

apply FUN to array's rows

2 apply FUN to array's columns

## The 6 common higher-order functions

Reduce(f, x, init, right = F, accumulate = F)

Filter(f, x)

Find(f, x, right = F, nomatch = NULL)

Map(f, ...)

Negate(f)

Position(f,x,right = F,nomatch = NA\_integer\_)

### Others

optimise()...One Dimensional Optimization

merge(a,b)... merge two data frames by common columns or row names

xtabs(a b,data=x)

a contingency table from cross-classifying factors

aggregate(x,by,FUN)

splits the data frame x into subsets, computes summary statistics for each, and returns the result in a convenient form; by is a list of grouping elements, each as long as the variables in x

stack(x, ...) . transform data available as separate columns in a data frame or list into a single column

unstack(x, ...) inverse of stack()

reshape(x, ...) reshapes a data frame between 'wide' format with repeated measurements in separate columns of the same record and 'long' format in separate records

⇒ use: (direction="wide") or (direction="long")

# Optimization and model fitting

nlm(f,p)..... minimize function f using a Newton-type algorithm with starting values p

 $\Rightarrow$  for terms made of nonlinear components, use:  $I(x*y) + I(x^2)$ 

glm(formula,family=)

fit generalized linear models, specified by giving a symbolic description of the linear predictor and a description of the error distribution

 $\Rightarrow$  see ?family: family is a description of the error distribution and link function to be used in the model

nls(formula) nonlinear least-squares estimates of the nonlinear model parameters

spline(x,y=) cubic spline interpolation

loess(formula) fit a polynomial surface using local fitting

Many of the formula-based modeling functions have several common arguments: data= the data frame for the formula variables, subset= a subset of variables used in the fit, na.action= action for missing values: "na.fail", "na.omit", or a function.

### Statistics

help.search("test") gives you a range of validity tests such as t.test(), binom.test(), prop.test(), power.t.test(), pairwise.t.test(), ...

## Model Analysis

The following generics often apply to model fitting functions

predict(fit,...) predictions from fit based on input data

coef(fit) .... returns the estimated coefficients (sometimes with their standard-errors)

residuals(fit) returns the residuals

df.residual(fit) returns the number of residual degrees of freedom

deviance(fit) returns the deviance

fitted(fit)..returns the fitted values

logLik(fit)...computes the logarithm of the likelihood and the number of parameters

AIC(fit) ..... computes the Akaike information criterion or AIC

aov(formula) analysis of variance model

anova(fit,...) analysis of variance (or deviance) tables for one or more fitted model objects

density(x)...kernel density estimates of x

# Distribution Functions

All of the following commands can be used by replacing the letter r with d, p or q to get the probability function, the cumulative probability function, and the value of quantile, respectively.

dfunc(x, ...) . Cumulative Density Function
pfunc(q, ...) . Probability Distribution Function
qfunc(p, ...) . Quantile Function
⇒ prob.: with 0

# Functions (yfunc)

ynorm(n, mean=0, sd=1) Gaussian  $\Phi(x)$ : pnorm(x)  $\Phi^{-1}(x)$ : anorm(x) exponential  $y \exp(n, \text{rate}=1)$ gamma ygamma(n, shape, scale=1) ypois(n, lambda) Poisson Weibull yweibull(n, shape, scale=1) ycauchy(n, location=0, scale=1) Cauchy beta ybeta(n, shape1, shape2) 'Student'-t yt(n, df)Fisher-Snedecor yf(n, df1, df2) $\Rightarrow$   $(F)(\chi^2)$ : ychisq(n, df) Pearson ygeom(n, prob) geometric hypergeometric yhyper(nn, m, n, k) logistic ylogis(n, location=0, scale=1) ylnorm(n, meanlog=0, sdlog=1) lognormal uniform yunif(n, min=0, max=1)

## Wilcoxon's statistics

ywilcox(nn, m, n) Wilcoxon Statistic
ysignrank(nn, n) Signed Rank Statistic

## Binomial Distributed

ybinom(n, size, prob) positive binomial ynbinom(n, size, prob) negative binomial

## Time Series Calculations $\rightarrow$ library(xts)

ts(x, start, end, frequency)

Create a time-series vector

 $\Rightarrow$  Time Series Object of 24 random variables over a two years monthly scale, starting from Jan 2010:

ts(rnorm(24), c(2010, 1), frequency=12)

xts(x, order.by=as.POSIXct(...))

Convert data vector to a timeseriesobject

- $\Rightarrow$  fit an AR(1) to x via an OLS regression: ar(x, order.max = 1, method = "ols")
- window(x).... Extracts the subset of the object x observed between the start and end of a timeseries object. (If a frequency is specified, the series is then re-sampled at the new frequency)
- ⇒ Resampling a timeseries for the month of November (every 11th month of a year) over the past couple of decades: window(x, start=c(2000, 11), frequency=T)
- $\Rightarrow$  Extract data between Jan 2000 and Dec 2015 from x: window(x, c(2000,1), c(2015,12))
- time(x)..... creates the vector of times at which a time series was sampled
- cycle(x)..... gives the positions in the cycle of each observation
- frequency(x) returns the number of samples per unit time and deltat the time interval between observations
- filter(x,filter)

applies linear filtering to a univariate time series or to each series separately of a multivariate time series

ar(x, order.max, method)

fit an autoregressive time series model to the data

Box.test(x, lag = p, type = c())

Compute the 'Box-Pierce' or 'LjungBox' test statistic for examining the
null hypothesis of independence in a
given time series.

Box-Pierce  $T * sum(rho[i]^2)$ 

Ljung-Box  $T(T+2)*sum(rho[i]^2/(T-j))$ 

## Plotting

- plot(x) ..... plot of the values of x (on the y-axis) ordered on the x-axis
- plot(x, y)... bivariate plot of x (on the x-axis) and y (on the y-axis)
- $\mbox{\sc hist}(x)$  ..... histogram of the frequencies of x
- curve(x)..... draws a curve corresponding to a function over the interval [from, to].
- dotchart(x)..if x is a data frame, plots a Cleveland dot plot (stacked plots line-by-line and column-by-column)
- pie(x) ..... circular pie-chart
- boxplot(x)... "box-and-whiskers" plot
- sunflowerplot(x, y)

id. than plot() but the points with similar coordinates are drawn as flowers which petal number represents the number of points

- stripplot(x) plot of the values of x on a line (an alternative to boxplot() for small sample sizes)
- $\mathtt{coplot}(\mathtt{x}^{\sim}|\ \mathtt{z})$  bivariate plot of  $\mathtt{x}$  and  $\mathtt{y}$  for each value or interval of values of  $\mathtt{z}$
- interaction.plot (f1, f2, y)

if f1 and f2 are factors, plots the means of y (on the y-axis) with respect to the values of f1 (on the x-axis) and of f2 (different curves); the option fun allows to choose the summary statistic of y (by default fun=mean)

matplot(x,y) bivariate plot of the first column of x vs. the first one of y, the second one of x vs. the second one of y, etc.

- fourfoldplot(x) visualizes, with quarters of circles, the association between two dichotomous variables for different populations (x must be an array with dim=c(2, 2, k), or a matrix with dim=c(2, 2) if k=1)
- assocplot(x) Cohen–Friendly graph showing the deviations from independence of rows and columns in a two dimensional contingency table
- mosaicplot(x) 'mosaic' graph of the residuals from a log-linear regression of a contingency table
- pairs(x).... if x is a matrix or a data frame, draws all possible bivariate plots between the columns of x
- ts.plot(x)...id. but if x is multivariate the series may have different dates and must have the same frequency
- $\mathtt{qqnorm}(\mathtt{x})\dots\mathtt{quantiles}$  of  $\mathtt{x}$  with respect to the values expected under a normal law
- qqplot(x, y) quantiles of y with respect to the quantiles of x
- filled.contour(x, y, z)

  id. but the areas between the contours are coloured, and a legend of the colours is drawn as well
- $\begin{array}{ccc} \mathtt{image(x,\ y,\ z)} & \mathrm{id.\ but\ with\ colours\ (actual\ data} \\ & \mathrm{are\ plotted)} \end{array}$

stars(x)

if x is a matrix or a data frame, draws a graph with segments or a star where each row of x is represented by a star and the columns are the lengths of the segments

symbols(x, y, ...)

draws, at the coordinates given by x and y, symbols (circles, squares, rectangles, stars, thermometres or "boxplots") which sizes, colours ... are specified by supplementary arguments

termplot(mod.obj)

plot of the (partial) effects of a regression model (mod.obj)

## Plot Modifiers

The following parameters are common to many plotting functions

- add=F if TRUE superposes the plot on the previous one (if it exists)
- axes=T if FALSE does not draw the axes and the box
- type="" specifies the type of plot

"p" points

"b" points connected by lines

"o" id. but the lines are over the points

"h" vertical lines

"s" steps, the data are represented by the top of the vertical lines

"S" id. but the data are represented by the bottom of the vertical lines

- xlim=, ylim= specifies the lower and upper limits of the axes
- ⇒ upper and lower limits: xlim=c(1, 10)
  or xlim=range(x)
  - xlab=, ylab= annotates the axes, must be variables of mode character
  - main= main title, must be a variable of mode character

- sub= sub-title (written in a smaller font)

## Low-level plotting commands

- graphics.off() closes before opened plot. it is implemented by calling dev.off() as many times as necessary.
- $\Rightarrow$  equvialent commands for rgl, iplots packages: rgl.close(), iplot.off()

lines(x, y)..id. but with lines

text(x, y, labels...)

adds text given by labels at coordinates (x,y); a typical use is: plot(x, y, type="n"); text(x, y, names)

mtext(text, side=3, line=0, ...)
 adds text given by text in the margin
 specified by side (see axis() below);
 line specifies the line from the plotting
 area

arrows(x0, y0, x1, y1, angle= 30, code=2)
id. with arrows at points (x0,y0) if
code=2, at points (x1,y1) if code=1, or
both if code=3; angle controls the angle from the shaft of the arrow to the
edge of the arrow head

abline(a,b).. draws a line of slope b and intercept a

abline(h=y).. draws a horizontal line at ordinate

abline(v=x).. draws a vertical line at abcissa x

abline(lm.obj) draws regression line given by lm.obj rect(x1, y1, x2, y2)

draws a rectangle which left, right, bottom, and top limits are x1, x2, y1, and y2, respectively

- polygon(x, y) draws a polygon linking the points with coordinates given by x and y
- title() ..... adds a title and optionally a sub-title
- axis(side, vect) adds an axis at the bottom (side=1), on the left (2), at the top (3), or on the right (4); vect (optional) gives the abcissa (or ordinates) where tick-marks are drawn
- rug(x) ...... draws the data x on the x-axis as small vertical lines
- locator(n, type="n", ...) returns the coordinates (x,y) after the user has clicked n times on the plot with the mouse; also draws symbols  $({\tt type="p"})$  or lines  $({\tt type="l"})$  with respect to optional graphic parameters
- $\Rightarrow$  by default nothing is drawn: type="n"

## Graphical parameters

These can be set globally with par(...); many can be passed as parameters to plotting commands.

- adj ...... controls text justification (0 left-justified, 0.5 centred, 1 right-justified)
- bty...... controls the type of box drawn around the plot, allowed values are: "o", "1", "7", "c", "u" or "] " (the box looks like the corresponding character)
- $\Rightarrow$  if bty="n": the box is not drawn
- cex...... a value controlling the size of texts and symbols with respect to the default; the following parameters have the same control for...

cex.axis	numbers on the axes
cex.lab	the axis labels
cex.mair	the title
cex.sub	the sub-title
col	controls the color of symbols and lines; use color names e.g. "red", "blue" or as "#RRGGBB"
$\Rightarrow$ see: crainbow	colors(), rgb(), hsv(), gray() and g()
	cex there are: col.axis, col.lab, .n, col.sub
font	an integer which controls the style of text (1: normal, 2: italics, 3: bold, 4: bold italics)
	<pre>cex there are: font.axis, font.lab, ain, font.sub</pre>
las	an integer which controls the orientation of the axis labels (0: parallel to the axes, 1: horizontal, 2: perpendicular to the axes, 3: vertical)
lty	controls the type of lines, can be an integer or string (1: "solid", 2: "dashed", 3: "dotted", 4: "dotdash", 5: "longdash", 6: "twodash", or a string of up to eight characters (between "0" and "9") which specifies alternatively the length, in points or pixels, of the drawn elements and the blanks, for example lty="44" will have the same effect than lty=2
lwd	a numeric which controls the width of lines, default ${\bf 1}$
	a vector of 4 numeric values which control the space between the axes and the border of the graph of the form c(bottom, left, top, right), the default values are c(5.1, 4.1, 4.1, 2.1)
	a vector of the form c(nr,nc) which partitions the graphic window as a ma- trix of nr lines and nc columns, the plots are then drawn in columns
mfrow	id. but the plots are drawn by row

pch controls the type of symbol, either an integer between 1 and 25, or any single character within ""
ps an integer which controls the size in points of texts and symbols
pty a character which specifies the type of the plotting region, "s": square, "m": maximal
tck a value which specifies the length of tick-marks on the axes as a fraction of the smallest of the width or height of the plot; if tck=1 a grid is drawn
tcl a value which specifies the length of tick-marks on the axes as a fraction of the height of a line of text (by default tcl=-0.5)
<pre>xaxtif xaxt="n" the x-axis is set but not</pre>
<pre>yaxtif yaxt="n" the y-axis is set but not</pre>

# Lattice (Trellis) graphics

Use panel= to define a custom panel function (see apropos("panel") and ?llines). Lattice functions return an object of class trellis and have to be printed to produce the graph. Use print(xyplot(...)) inside functions where automatic printing doesn't work. Use lattice.theme and lset to change Lattice defaults.

xyplot(y~x)..bivariate plots (with many functionalities)

 $\begin{array}{ccc} \texttt{barchart}(\texttt{y}\tilde{\texttt{x}}) & \text{histogram of the values of } \texttt{y} \text{ with} \\ & \text{respect to those of } \texttt{x} \end{array}$ 

dotplot(y~x) Cleveland dot plot (stacked plots line-by-line and column-by-column)

 ${\tt densityplot(~x)} \ \ {\rm density} \ {\rm functions} \ {\rm plot}$ 

histogram(~x) histogram of the frequencies of x

bwplot(y~x).. "box-and-whiskers" plot

 $\begin{array}{c} \mathtt{qqmath(\tilde{x})} \ldots \mathtt{quantiles} \ \mathrm{of} \ x \ \mathrm{with} \ \mathrm{respect} \ \mathrm{to} \ \mathrm{the} \ \mathrm{values} \\ \mathrm{expected} \ \mathrm{under} \ \mathrm{a} \ \mathrm{theoretical} \ \mathrm{distribution} \end{array}$ 

stripplot(y~x) single dimension plot, x must be numeric, y may be a factor

splom(~x).... matrix of bivariate plots

parallel(~x) parallel coordinates plot levelplot(z~x\*y|g1\*g2)

coloured plot of the values of z at the coordinates given by x and y (x, y and z are all of the same length)

wireframe(z~x\*y|g1\*g2)
3d surface plot

In the normal Lattice formula, y x|g1\*g2 has combinations of optional conditioning variables g1 and g2 plotted on separate panels. Lattice functions take many of the same arguments as base graphics plus also  $\mathtt{data}$ = the data frame for the formula variables and  $\mathtt{subset}$ = for subsetting.

# Programming

Use curly braces  $\{\}$  around statements

function( arglist ) expr # function definition
return(value) if(cond) expr
if(cond) cons.expr else alt.expr
for(var in seq) expr
while(cond) expr
repeat expr
break
next

10

do.call(funname, args)

executes a function call from the name of the function and a list of arguments to be passed to it
