R QUICK REFERENCE CARD

Frequently used R commands - Version v1.3 August 2014

A first version of this qrc was created by Tom Short, EPRI PEAC, in 2004-10-21. I modified the document so that it fits my other reference cards; all of its original content has been preserved and, in some cases only, expanded.

Basic Operations

Help

Most R functions have online documentation.

help(topic). documentation on topic

?topic id.

help.search("topic")

search the help system

apropos("topic")

the names of all objects in the search list matching the regular expression "topic"

help.start() start the HTML version of help

Fundamentals

 \leftarrow assign to an object, equivalent to =(?)

<<-..... lexical assignment (*NOT* global assignment)

getwd()..... get the working directory

setwd() set the working directory

system().... call the operating system (shell)

Sys.Date() .. Retreive current date, without time
system.time()

time an evaluation

Sys.sleep(). pause

 $\mathtt{str}(\mathtt{a})$ display the internal $[\mathtt{str}]$ ucture of an R object a

summary(a).. gives a "summary" of a, usually a statistical summary but it is *generic* meaning it has different operations for different classes of a

ls() show objects in the search path; specify pat="pat" to search on a pattern

 ${\tt ls.str()}\ldots$ ${\tt str()}$ for each variable in the search path

dir() show files in the current directory

methods(a).. shows S3 methods of a methods(class=class(a))

lists all the methods to handle objects of class a

Input and output

load() load the datasets written with save

data(x)..... loads specified data set

library(x).. load add-on packages

save(file,...)

saves the specified objects (...) in the XDR platform-independent binary format

save.image(file)

saves all objects

cat(..., file="", sep=" ")

prints the arguments after coercing to character; sep is the character separator between arguments

format(x,...)

format an R object for pretty printing

Read from File

read.table(file)

reads a file in table format and creates a data frame from it; the default separator sep="" is any whitespace

read.csv("filename",header=T)

id. but with defaults set for reading comma-delimited files

read.csv2("filename",header=T)

id. but with defaults set for reading semicolon-delimited files and dec=","

read.delim("filename",header=T)

id. but with defaults set for reading tab-delimited files

read.fwf(file,widths,header=F,sep="\t",as.is=F)

read a table of [f]ixed [w]idth [f]ormatted data into a 'data.frame'; widths is an integer vector, giving the widths of the fixed-width fields

Read Options

-as.is=TRUE

to prevent character vectors from being converted to factors

-blank.lines.skip=TRUE

blank lines in the input are ignored.

-fill=TRUE

in case the rows have unequal length, blank fields are implicitly added

-header=TRUE

to read the first line as a header of column names

-comment.char=""

to prevent "#" from being interpreted as a comment

-skip=n to skip n lines before reading data

Write to file

write.table(x,file="",row.names=T,col.names=T, sep=" ")

prints x after converting to a data frame;
if quote is TRUE, character or factor
columns are surrounded by quotes (");
sep is the field separator; eol is the
end-of-line separator; na is the string
for missing values; use col.names=NA
to add a blank column header to get
the column headers aligned correctly
for spreadsheet input

Clipboard

On windows, the file connection can also be used with description = "clipboard".

- ⇒ To read a table copied from Excel, use: x <- read.delim("clipboard")</pre>
- ⇒ To write a table to the clipboard for Excel, use:

write.table(x,"clipboard",sep="\t",col.names=NA)

Unix users wishing to write to the primary selection may be able to do so via 'xclip', for example by

 \Rightarrow writes data 'x' to clipboard: pipe('xclip -i', x)

For database interaction, see packages RODBC, DBI, RMySQL, RPgSQL, and ROracle. See packages XML, hdf5, netCDF for reading other file formats.

Data creation

- c(...) generic function to concatenate arguments with the default forming a vector; with recursive=T descends through lists combining all elements into one vector
- from:to..... generates a sequence; ":" has operator priority; 1:4 + 1 is "2,3,4,5"
- seq(from,to) generates a sequence by= specifies increment; length= specifies desired length
- rep(x,times) replicate x times; use each= to repeat
 "each" element of x each times;
- \Rightarrow rep(c(1,2,3),2): 1 2 3 1 2 3
- \Rightarrow rep(c(1,2,3),each=2): 1 1 2 2 3 3

data.frame(...)

create a data frame of the named or unnamed arguments

 \Rightarrow $\;$ shorter vectors are being recycled to the length of the longest:

d..ame(v=1:4,ch=c("a","B","c","d"),n=10)

list(...) ... create a list of the named or unnamed arguments

 \Rightarrow use: list(a=c(1,2),b="hi",c=3i)

array(x,dim=)

array with data x; specify dimensions like dim=c(3,4,2); elements of x recycle if x is not long enough

matrix(x,nrow=,ncol=)

matrix; elements of x recycle

factor(x,levels=)

encodes a vector x as a factor

gl(n,k,length=n*k,labels=1:n)

generate levels (factors) by specifying the pattern of their levels; ${\tt k}$ is the number of levels, and ${\tt n}$ is the number of replications

expand.grid()

a data frame from all combinations of the supplied vectors or factors

rbind(...) .. combine arguments by rows for matrices, data frames, and others

cbind(...) .. id. by columns

append column named ''colName'' to matrix x: cbind(x, colName=c(1,2,3))

Slicing and extracting data

Indexing vectors

x[n]	n^{th} element
x[-n]	all but the n^{th} element
x[-length(x)]	all but last element
x[1:n]	first elements
x[-(1:n)]	elements from $n+1$ to the end
x[c(1,4,2)]	specific elements

x["name"]	element named "name"
x[x > 3]	all elements greater than 3
x[x > 3 & x < 5]	all elements between 3 and 5 $$
\Rightarrow elements in	the given set:
x[x %in% c("	a","and","the")]

Indexing lists

x[n]	list with elements n
x[[n]]	\mathbf{n}^{th} element of the list
x[["name"]]	element of the list named "name"
x\$name	id.

Indexing matrices

x[i,j]	element at row i , column j
x[i,]	row i
x[,j]	column j
x[,c(1,3)]	columns 1 and 3
x["name",]	row named "name"

Indexing data frames

matrix indexing plus the following

x[["name"]] column named "name"
x\$name id.

Variable information

 $\overline{\text{is.na}(x), \text{is.null}(x), \text{is.array}(x), \text{is.data.frame}(x), \dots}$

methods(is). list all available typetests

 ${\tt methods(as)}$. list of all variable conversions

any(x)..... any TRUE elements of x?

all(x)..... all TRUE elements of x?

length(x) ... number of elements in x

 ${\tt rle(x)}$ length of consecutive elements in ${\tt x}$

dim(x) Retrieve or set the dimension of an object; $dim(x) \leftarrow c(3,2)$

dimnames(x). Retrieve or set the dimension names of an object

attr(x, which)

get or set the attribute which or

get or set the attribute which of x attributes(obj)

get or set the list of attributes of obj

Data selection and manipulation

which.max(x) returns the index of the greatest element of x

which.min(x) returns the index of the smallest element of x

rev(x) reverses the elements of x

 $\mathtt{sort}(\mathtt{x})$ sorts the elements of \mathtt{x} in increasing order

rev(sort(x)) to sort in decreasing order

cut(x,breaks)

divides x into intervals (factors); breaks is the number of cut intervals or a vector of cut points

x %in% y..... logical vector indicating if there is a match or not for its left operand

 $\mathtt{match}(\mathtt{x},\ \mathtt{y})$. returns a vector of the same length than \mathtt{x} with the elements of \mathtt{x} which are in \mathtt{y} (NA otherwise)

which(x == a)

returns a vector of the indices of \mathbf{x} if the comparison operation is true (T), in this example the values of \mathbf{i} for which $\mathbf{x}[\mathbf{i}] == \mathbf{a}$ (the argument of this function must be a variable of mode logical)

choose(n, k) computes the combinations of k events among n repetitions = n!/[(n-k)!k!]

combn(n, k). Generate All Combinations of n Elements, Taken m at a Time.

 ${\tt na.omit(x)}$.. suppresses the observations with missing data (NA) (suppresses the corresponding line if ${\tt x}$ is a matrix or a data frame)

complete.cases(x[n],x[n])

allows removement of 'na's by using part of the dataframe

⇒ skip all rows in data frame x, where 'na'
appears in column 5 or 6:
x[complete.cases(x[,5:6]),]

 ${\tt na.fail}({\tt x})$.. returns an error message if ${\tt x}$ contains at least one NA

unique(x) ... if x is a vector or a data frame, returns a similar object but with the duplicate elements suppressed

duplicated(x)

returns a logical vector indicating which elements (rows) of a vector or data frame are duplicates

table(x).... returns a table with the numbers of the differents values of x (typically for integers or factors)

subset(x, ..)

returns a selection of x with respect to criteria (..., typically comparisons: x\$V1 < 10); if x is a data frame, the option select gives the variables to be kept or dropped using a minus sign

sample(x, size)

resample randomly and without replacement \mathtt{size} elements in the vector \mathtt{x} , the option $\mathtt{replace} = \mathtt{TRUE}$ allows to resample with replacement

prop.table(x,margin=)

table entries as fraction of marginal table

Characters (Strings)

substr(x,start,stop)
substrings in a character vector

⇒ can also assign, as:
 substr(x, start, stop) <- value
strsplit(x,split)</pre>

split x according to the substring split

grep(pattern,x)

searches for matches to pattern within x; see ?regex

gsub(pattern,replacement,x)

replacement of matches determined by regular expression matching sub() is the same but only replaces the first occurrence.

tolower(x).. convert to lowercase

toupper(x) .. convert to uppercase
match(x,table)

a vector of the positions of first matches for the elements of x among table

x %in% table

id. but returns a logical vector

pmatch(x,table)

partial matches for the elements of x among table

nchar(x).... number of characters

assign..... assign a value to a name

Dates and Times

The class Date has dates without times. POSIXct has dates and times, including time zones. Comparisons (e.g. >), seq(), and difftime() are useful. Date also allows + and -. ?DateTimeClasses gives more information. See also package chron.

as.Date(s) .. and

~ ~	Т	വ	TV	a +	(s)
as	. г	CO	ıΤV	しし	(8)

convert to the respective class; format(dt) converts to a string representation. The default string format is "2001-02-21". These accept a second argument to specify a format for conversion. Some common formats are:

	version. Donne common formats are.
%a, %A	Abbreviated and full
	weekday name.
%b, %B	Abbreviated and full month name.
%d	Day of the month $(01-31)$.
%Н	Hours $(00-23)$.
%I	Hours $(01-12)$.
%ј	Day of year (001–366).
%m	Month (01–12).
%M	Minute (00–59).
%p	AM/PM indicator.
%S	Second as decimal number (00–61).
%U	Week $(00-53)$; the first Sunday as day 1 of week 1.
%w	Weekday $(0-6, \text{Sunday is } 0)$.
%W	Week $(00-53)$; the first Monday as day 1 of week 1.
%X	Same as " $\%$ Y- $\%$ m- $\%$ d"
%у	Year without century (00–99). (Don't use due to ambiguousness!)
%Y	Year with century.
%z	(output only.) Offset from Greenwich; -0800 is 8 hours west of.
%Z	(output only.) Time zone as a character string (empty if not available).

Where leading zeros are shown they will be used on output but are optional on input. See ?strftime. as.POSIXct(strptime(, format=)) format()

Setting the C locale will overcome NA issues which emerge on some systems due to format incongruencies:

lct <- Sys.getlocale(LC_TIME)
$Sys.setlocale(\ddot{L}C_{-}TIME; \ddot{C})$
x <- "1919-01-31"
<pre>as.Date(x,)</pre>
•••
$Sys.setlocale(\ddot{L}C_{-}TIME; lct)$

Math

sin,cos,tan,asin,acos,atan,atan2,log,log10,exp

Basic Math Operations		
%%, %/% modulo/quotient, remainder		
max(x) maximum of the elements of x		
$\min(x)$ minimum of the elements of x		
range(x)id. then c(min(x), max(x))		
$\operatorname{sum}(x)$ sum of the elements of x		
$\begin{array}{ccc} \mathtt{diff}(\mathtt{x}) \ldots \ldots & \mathrm{lagged} \ \mathrm{and} \ \mathrm{iterated} \ \mathrm{differences} \ \mathrm{of} \ \mathrm{vector} \ \mathtt{x} \end{array}$		
$\mathtt{prod}(\mathtt{x}) \ldots$ product of the elements of \mathtt{x}		
$mean(x) \dots mean of the elements of x$		
<pre>median(x) median of the elements of x quantile(x,probs=)</pre>		
sample quantiles corresponding to given probabilities (default: 0,.25,.5,.75,1)		
weighted.mean(x, w) mean of x with weights w		
$\mathtt{rank}(\mathtt{x})\dots$ ranks of the elements of \mathtt{x}		
$\operatorname{var}(x)$ or $\operatorname{cov}(x)$ variance of the elements of x (calculated on $n-1$); if x is a matrix or a data frame, the variance-covariance matrix is calculated		
sd(x) standard deviation of x		
<pre>cor(x) correlation matrix of x if it is a matrix</pre>		
<pre>var(x, y) or cov(x, y) covariance between x and</pre>		

those of y if they are matrices or data

frames

cor(x, y) ... linear correlation between x and y, or correlation matrix if they are matrices or data frames

round(x, n), rounds the elements of x to n decimals

log(x, base) computes the logarithm of x with base

scale(x).... if x is a matrix, centers and reduces the data; to center only use the option center=F, to reduce only scale=F (by default center=T, scale=T)

pmin(x,y,...) a vector which ith element is the minimum of x[i], y[i], ...

pmax(x,y,..) . id. for the maximum

 $cumsum(x) \dots a vector which ith element is the sum$ from x[1] to x[i]

cumprod(x).. id. for the product

cummin(x) ... id. for the minimum

cummax(x) ... id. for the maximum

Arithmetic & Boolean Operators

x + y	addition
х - у	subtraction
x * y	multiplication
x / y	division
x ^ y	exponentiation
x %% y	modular arithmetic
x %/% y	integer division
X %*% Y	matrix multiplication
x == y	test for equality
x <= y	test for less-than-or-equal
x >= y	test for greater-than-or-equal
x && y	boolean and for scalars
x II y	boolean or for scalars
х & у	boolean and for vectors (vector x,y,result)
хІу	boolean or for vectors (vector x,y,result)
! x	boolean negation

Complex Numbers

union(x,y), intersect(x,y), setdiff(x,y), setequal(x,y)
is.element(el.set)

"set" functions

Re(x).... real part of a complex number

Im(x)..... imaginary part

 $Mod(x) \dots modulus; abs(x) is the same$

Arg(x) angle in radians of the complex number

Conj(x)..... complex conjugate

convolve(x,y)

compute the several kinds of convolutions of two sequences

fft(x)..... Fast Fourier Transform of an array

mvfft(x)..... FFT of each column of a matrix
filter(x,filter)

applies linear filtering to a univariate time series or to each series separately of a multivariate time series

Many math functions have a logical parameter na.rm=F to specify missing data (NA) removal.

Matrices

%o%, outer() outer products on arrays

A %*% B..... multiplication of A and B

kronecker ... kronecker products on arrays

 ${\tt t(x)} \; \dots \quad {\rm transpose}$

diag(x)..... diagonal

solve(a,b) .. solves a %*% x = b for x

solve(a).... matrix inverse of a

rowsum(x) ... sum of rows for a matrix-like object;

rowSums(x).. is a faster version

colsum(x) ... sum of columns for a matrix-like object;

 ${\tt colSums(x)}$.. id. for columns

rowMeans(x). fast version of row means

colMeans(x). id. for columns

Advanced data processing and HOFs

Apply functions to elements

The base apply family of function is standardized and parallelized by the plyr package.

apply(X,INDEX,FUN=)

a vector or array or list of values obtained by applying a function FUN to margins (INDEX) of X

lapply(X,FUN)

apply FUN to each element of the list X

tapply(X,INDEX,FUN=)

apply FUN to each cell of a ragged array given by X with indexes INDEX

by(data,INDEX,FUN)

apply FUN to data frame ${\tt data}$ subsetted by INDEX

Options for INDEX

1 apply FUN to array's rows

2 apply FUN to columns

The 6 common higher-order functions

Reduce(f, x, init, right = F, accumulate = F)

Filter(f, x)

Find(f, x, right = F, nomatch = NULL)

Map(f, ..)

Negate(f)

Position(f,x,right = F,nomatch = NA_integer_)

Others

optimise().. One Dimensional Optimization

merge(a,b).. merge two data frames by common columns or row names

xtabs(a b,data=x)

a contingency table from cross-classifying factors

aggregate(x,by,FUN)

splits the data frame x into subsets, computes summary statistics for each, and returns the result in a convenient form; by is a list of grouping elements, each as long as the variables in x

stack(x, ..) . transform data available as separate columns in a data frame or list into a single column

unstack(x, ..)

inverse of stack()

reshape(x, ..)

reshapes a data frame between 'wide' format with repeated measurements in separate columns of the same record and 'long' format in separate records

⇒ use: (direction="wide") or (direction="long")

Optimization and model fitting

optim(par, fn, method = c("Nelder-Mead", "BFGS", ..): general purpose optimization; par is initial values, fn is function to optimize (normally minimize)

nlm(f,p).... minimize function f using a Newtontype algorithm with starting values p

glm(formula,family=)

fit generalized linear models, specified by giving a symbolic description of the linear predictor and a description of the error distribution

⇒ see ?family: family is a description of the error distribution and link function to be used in the model

nls(formula) nonlinear least-squares estimates of the nonlinear model parameters

spline(x,y=) cubic spline interpolation

loess(formula) fit a polynomial surface using local fitting Many of the formula-based modeling functions have several common arguments: data= the data frame for the formula variables, subset= a subset of variables used in the fit, na.action= action for missing values: "na.fail", "na.omit", or a function. Statistics help.search("test") gives you a range of validity tests such as t.test(), binom.test(), prop.test(), power.t.test(), pairwise.t.test(), ... Model Analysis The following generics often apply to model fitting functions predict(fit,...) data df.residual(fit) of freedom times with their standard-errors)

predictions from fit based on input returns the number of residual degrees coef(fit) ... returns the estimated coefficients (some-

residuals(fit) returns the residuals deviance(fit) returns the deviance

fitted(fit). returns the fitted values

logLik(fit). computes the logarithm of the likelihood and the number of parameters

AIC(fit).... computes the Akaike information criterion or AIC

aov(formula) analysis of variance model

anova(fit,...)

analysis of variance (or deviance) tables for one or more fitted model obiects

density(x).. kernel density estimates of x

Distributions

```
rnorm(n, mean=0, sd=1)
               Gaussian (normal)
rexp(n, rate=1)
               exponential
rgamma(n, shape, scale=1)
               gamma
rpois(n, lambda)
               Poisson
rweibull(n, shape, scale=1)
               Weibull
rcauchy(n, location=0, scale=1)
               Cauchy
rbeta(n, shape1, shape2)
               beta
rt(n, df) ... 'Student' (t)
rf(n, df1, df2)
               Fisher-Snedecor (F) (\chi^2)
rchisq(n, df)
               Pearson
rbinom(n, size, prob)
              binomial
rgeom(n, prob)
               geometric
rhyper(nn, m, n, k)
               hypergeometric
rlogis(n, location=0, scale=1)
               logistic
rlnorm(n, meanlog=0, sdlog=1)
              lognormal
rnbinom(n, size, prob)
              negative binomial
runif(n, min=0, max=1)
               uniform
rwilcox(nn. m. n)
              rsignrank(nn, n) Wilcoxon's statis-
All these functions can be used by replacing the letter r
```

with d, p or q to get, respectively, the probability density (dfunc(x, ...)), the cumulative probability density (pfunc(x, ...)), and the value of quantile (qfunc(p, ...),with 0).

Programming

Use curly braces {} around statements

function(arglist) expr # function definition return(value) if(cond) expr if(cond) cons.expr else alt.expr for(var in seq) expr while(cond) expr repeat expr break

ifelse(test, yes, no) a value with the same shape as test filled with elements from either yes or

do.call(funname, args)

nο

executes a function call from the name of the function and a list of arguments to be passed to it

Plotting

next

plot(x)..... plot of the values of x (on the y-axis) ordered on the x-axis

plot(x, y).. bivariate plot of x (on the x-axis) and y (on the y-axis)

hist(x)..... histogram of the frequencies of x

barplot(x) .. histogram of the values of x; use horiz=F for horizontal bars

dotchart(x). if x is a data frame, plots a Cleveland dot plot (stacked plots line-by-line and column-by-column)

pie(x)..... circular pie-chart

boxplot(x).. "box-and-whiskers" plot

sunflowerplot(x, y)

id. than plot() but the points with similar coordinates are drawn as flowers which petal number represents the number of points

stripplot(x) plot of the values of x on a line (an alternative to boxplot() for small sample sizes)

coplot(x~| z)

bivariate plot of \mathbf{x} and \mathbf{y} for each value or interval of values of \mathbf{z}

interaction.plot (f1, f2, y)

if $\mathtt{f1}$ and $\mathtt{f2}$ are factors, plots the means of y (on the y-axis) with respect to the values of $\mathtt{f1}$ (on the x-axis) and of $\mathtt{f2}$ (different curves); the option \mathtt{fun} allows to choose the summary statistic of y (by default $\mathtt{fun=mean}$)

matplot(x,y) bivariate plot of the first column of x vs. the first one of y, the second one of x vs. the second one of y, etc.

fourfoldplot(x)

visualizes, with quarters of circles, the association between two dichotomous variables for different populations (x must be an array with $\dim = c(2, 2, k)$, or a matrix with $\dim = c(2, 2)$ if k = 1)

assocplot(x) Cohen-Friendly graph showing the deviations from independence of rows and columns in a two dimensional contingency table

mosaicplot(x)

'mosaic' graph of the residuals from a log-linear regression of a contingency table

pairs(x)..... if x is a matrix or a data frame, draws all possible bivariate plots between the columns of x

 $\label{eq:plot.ts} \begin{tabular}{ll} \tt plot.ts(x) ... if x is an object of class "ts", plot of x with respect to time, x may be multivariate but the series must have the same frequency and dates x and x of the same frequency and dates x of the same frequency and x of the same frequency a$

ts.plot(x).. id. but if x is multivariate the series may have different dates and must have the same frequency

 $\begin{array}{c} \mathtt{qqnorm(x)} \ \dots \ \mathrm{quantiles} \ \mathrm{of} \ x \ \mathrm{with} \ \mathrm{respect} \ \mathrm{to} \ \mathrm{the} \ \mathrm{values} \\ \mathrm{expected} \ \mathrm{under} \ \mathrm{a} \ \mathrm{normal} \ \mathrm{law} \end{array}$

qqplot(x, y) quantiles of y with respect to the quantiles of x

contour(x, y, z)

contour plot (data are interpolated to
draw the curves), x and y must be vectors and z must be a matrix so that
dim(z)=c(length(x), length(y)) (x
and y may be omitted)

filled.contour(x, y, z)

id. but the areas between the contours are coloured, and a legend of the colours is drawn as well

image(x, y, z)

id. but with colours (actual data are plotted)

persp(x, y, z)

id. but in perspective (actual data are plotted)

symbols(x, y, ..)

draws, at the coordinates given by \mathbf{x} and \mathbf{y} , symbols (circles, squares, rectangles, stars, thermometres or "boxplots") which sizes, colours .. are specified by supplementary arguments

termplot(mod.obj)

plot of the (partial) effects of a regression model (mod.obj)

Plot Modifiers

The following parameters are common to many plotting functions

add=F if TRUE superposes the plot on the previous one (if it exists)

axes=T if FALSE does not draw the axes and the box

type="p" specifies the type of plot, "p":
 points, "1": lines, "b": points
 connected by lines, "o": id. but
 the lines are over the points, "h":
 vertical lines, "s": steps, the data
 are represented by the top of the
 vertical lines, "S": id. but the
 data are represented by the bottom of the vertical lines

xlim=, ylim= specifies the lower and upper limits of the axes, for example with

xlim=c(1, 10) or xlim=range(x)

xlab=, ylab= annotates the axes, must be vari-

ables of mode character
main= main title, must be a variable of

mode character

sub= sub-title (written in a smaller font)

Low-level plotting commands

dev.new() ... open a new graphics device (typically a window). see similar in help.

lines(x, y). id. but with lines

text(x, y, labels...)

adds text given by labels at coordinates (x,y); a typical use is: plot(x, y, type="n"); text(x, y, names)

mtext(text, side=3, line=0, ..)
 adds text given by text in the margin
 specified by side (see axis() below);
 line specifies the line from the plotting
 area

segments(x0, y0, x1, y1) draws lines from points (x0,y0) to points (x1,y1)

arrows(x0, y0, x1, y1, angle= 30, code=2)
 id. with arrows at points (x0,y0) if
 code=2, at points (x1,y1) if code=1, or
 both if code=3; angle controls the an gle from the shaft of the arrow to the
 edge of the arrow head

abline(a,b) . draws a line of slope b and intercept a		
${\tt abline(h=y)} \ . \ {\rm draws} \ a \ horizontal \ line \ at \ ordinate \ y$		
abline(v=x). draws a vertical line at abcissa x $abline(lm.obj)$		
draws regression line given by lm.obj		
rect(x1, y1, x2, y2)		
draws a rectangle which left, right, bottom, and top limits are x1, x2, y1, and y2, respectively		
polygon(x, y)		
draws a polygon linking the points with coordinates given by \mathbf{x} and \mathbf{y}		
legend(x, y, legend)		
adds the legend at the point (x,y) with the symbols given by legend. You may as well add "bottom", "topleft" etc. in place of coordinates x,y manually		
title() adds a title and optionally a sub-title		
axis(side, vect)		
adds an axis at the bottom (side=1), on the left (2), at the top (3), or on the right (4); vect (optional) gives the abcissa (or ordinates) where tick-marks are drawn		
rug(x) draws the data x on the x-axis as small vertical lines		
<pre>locator(n, type="n",)</pre>		
returns the coordinates (x, y) after the user has clicked n times on the plot with the mouse; also draws symbols (type="p") or lines (type="1") with respect to optional graphic parameters $()$		
\Rightarrow by default nothing is drawn: type="n"		
Graphical parameters		
These can be set globally with par(); many can be		

passed as parameters to plotting commands.

adj...... controls text justification (0 left-justified, 0.5 centred, 1 right-justified)

(ex.: bg="red", bg="blue", the list of the 657 available colours is displayed with colors())
bty controls the type of box drawn around the plot, allowed values are: "o", "l", "7", "c", "u" or "]" (the box looks like the corresponding character)
\Rightarrow if bty="n": the box is not drawn
cex a value controlling the size of texts and symbols with respect to the default; the following parameters have the same control for numbers on the axes, cex.axis, the axis labels, cex.lab, the title, cex.main, and the sub-title, cex.sub
col controls the color of symbols and lines; use color names e.g. "red", "blue" or as "#RRGGBB"
<pre>⇒ see: colors(), rgb(), hsv(), gray() and rainbow()</pre>
\Rightarrow as for cex there are: col.axis, col.lab, col.main, col.sub
<pre>font an integer which controls the style of</pre>
<pre>⇒ as for cex there are: font.axis, font.lab, font.main, font.sub</pre>
las an integer which controls the orientation of the axis labels (0: parallel to the axes, 1: horizontal, 2: perpendicular to the axes, 3: vertical)
<pre>lty controls the type of lines, can be an in- teger or string (1: "solid", 2: "dashed", 3: "dotted", 4: "dotdash", 5: "long- dash", 6: "twodash", or a string of up to eight characters (between "0" and "9") which specifies alternatively the length, in points or pixels, of the drawn elements and the blanks, for example lty="44" will have the same effect than lty=2</pre>
<pre>lwd a numeric which controls the width of</pre>

bg..... specifies the colour of the background

mar
mfrow id. but the plots are drawn by row
pch controls the type of symbol, either an integer between 1 and 25, or any single character within ""
ps an integer which controls the size in points of texts and symbols
pty a character which specifies the type of the plotting region, "s": square, "m": maximal
tck a value which specifies the length of tick-marks on the axes as a fraction of the smallest of the width or height of the plot; if tck=1 a grid is drawn
tcl a value which specifies the length of tick-marks on the axes as a fraction of the height of a line of text (by default tcl=-0.5)
<pre>xaxt if xaxt="n" the x-axis is set but not</pre>
<pre>yaxt if yaxt="n" the y-axis is set but not</pre>

Lattice (Trellis) graphics

Use panel= to define a custom panel function (see apropos("panel") and ?llines). Lattice functions return an object of class trellis and have to be printed to produce the graph. Use print(xyplot(...)) inside functions where automatic printing doesn't work. Use lattice.theme and lset to change Lattice defaults.

 $\ensuremath{\mathtt{xyplot(y^{x})}}$. bivariate plots (with many functionalities)

barchart(y~x)

histogram of the values of y with respect to those of x

dotplot(y~x) Cleveland dot plot (stacked plots line-by-line and column-by-column)

densityplot(~x)

density functions plot

histogram(~x)

histogram of the frequencies of x

bwplot(y~x). "box-and-whiskers" plot

 $\mathtt{qqmath(\tilde{x})}$.. quantiles of x with respect to the values expected under a theoretical distribution

stripplot(y~x)

single dimension plot, x must be numeric, y may be a factor

 $qq(y^*x)$ quantiles to compare two distributions, x must be numeric, y may be numeric, character, or factor but must have two 'levels'

splom(~x) ... matrix of bivariate plots

 $\verb|parallel(~x)| parallel coordinates plot|$

levelplot(z~x*y|g1*g2)

coloured plot of the values of z at the coordinates given by x and y (x, y and z are all of the same length)

wireframe($z^x*y|g1*g2$)

3d surface plot

 $cloud(z^*x*y|g1*g2)$

3d scatter plot

In the normal Lattice formula, y x|g1*g2 has combinations of optional conditioning variables g1 and g2 plotted on separate panels. Lattice functions take many of the same arguments as base graphics plus also \mathtt{data} = the data frame for the formula variables and \mathtt{subset} = for subsetting.
